Glossary

- added line. Added lines are lines added by added_line_options that extend across the plot region and perhaps across the plot region's margins. For instance, yline() adds horizontal lines at the specified values, whereas xline() adds vertical lines at the specified values. See [G-3] added_line_options.
- **addedlinestyle**. *addedlinestyle* specifies the overall look of added lines. The look of the added line is defined by the *linestyle* and whether or not the line extends through the margins of the plot region. See [G-4] *addedlinestyle* and [G-4] *linestyle*.
- **alignmentstyle**. *alignmentstyle* specifies how text is vertically aligned in a textbox, that is, whether text should appear on the baseline of a textbox, near the bottom, in the middle, or at the top. See [G-4] *alignmentstyle*.
- **anglestyle**. *anglestyle* specifies the angle at which text is to be displayed. The text could be displayed horizontally, vertically, at a 45-degree angle, or at any angle that you desire. See [G-4] *anglestyle*.
- **areastyle**. *areastyle* determines whether an area is to be outlined and filled, and, if so, in what color. The area might be an entire region, bars, an area under a curve, or other enclosed areas such as boxes in box plots. See [G-4] *areastyle*.
- aspect ratio. The aspect ratio of an object is the ratio of its width to its height. The aspect ratio of an overall Stata graph, also known as the available area, is controlled by specifying options ysize() or xsize(); see [G-3] region_options. graph describe will show you the ysize() and xsize() for a graph. The aspect ratio of the plot region is controlled by the aspect(#) option; see [G-3] aspect_option.
- available area. The available area is defined by the height and width of the overall graph area, as determined by options ysize(#) and xsize(#). See [G-3] region_options. Also see graph region and plot region.
- **axisstyle**. *axisstyle* is a composite style that holds and sets all attributes of an axis, including whether there are ticks, gridlines, and axis lines. Axis styles are used only in scheme files. You would rarely want to change axis styles. See [G-4] *axisstyle*.
- **baseline of text**. The baseline of text is the imaginary line on which text rests. Letters with descenders, such as p and g, will have the descenders fall beneath the baseline. See [G-4] *alignmentstyle*.
- bitmap image format. See image format, raster image format, and vector image format.
- **by-graph**. A by-graph is one graph that contains an array of separate graphs, each of the same type and each reflecting a different subset of the data. See [G-4] *bystyle* and [G-3] *by_option*.
- **bystyle**. *bystyle* specifies the overall look for by-graphs, including whether individual graphs have their own axes and labels or whether they are shared; whether the axis scales are different for each graph; and how close the graphs are to each other. See [G-4] *bystyle*.
- **clockposstyle**. *clockposstyle*, an integer from 0 to 12, specifies a location around a central point. *clockposstyle* of 0 is always allowed and refers to the center. See *compassdirstyle* for another method for specifying directions. See [G-4] *clockposstyle*.
- CMYK values. See cyan, magenta, yellow, and key or black (CMYK) values.
- color saturation. See intensity.
- **colorstyle**. *colorstyle* sets the color and opacity of graph components such as lines, backgrounds, and bars. See [G-4] *colorstyle*.

composite style. See style, composite style, and detail style.

connectstyle. *connectstyle* specifies if and how points in a scatterplot are to be connected. The most common choice is connect(1), which means to connect with straight lines. See [G-4] *connectstyle*.

cyan, magenta, yellow, and key or black (CMYK) values. Cyan, magenta, yellow, and key or black (CMYK) values are used to specify a color. For example, values 0, 0, 255, 0 specify yellow. Also see red, green, and blue (RGB) values and hue, saturation, and value (HSV) values.

detail style. See style, composite style, and detail style.

EMF. See Enhanced Metafile.

Encapsulated PostScript (EPS). Encapsulated PostScript (EPS) is a vector image format that is based on PostScript with certain restrictions, created by Adobe. The restrictions allow an EPS file to be included within other PostScript documents. A common use of EPS files is for them to contain a graph that can then be inserted into another document such as a report. An EPS file may contain both graphics and text. See [G-3] *eps_options*. Also see *image format*, *raster image format*, and vector image format.

Enhanced Metafile (EMF). Enhanced Metafile (EMF) was initially released in 1993 by Microsoft Corporation. EMF is primarily a vector format, although it can contain raster formats. EMF is also used as a graphics language for printer drivers and as a clipboard image format. Also see *image format*, raster image format, and vector image format.

EPS. See Encapsulated PostScript (EPS).

family and plottype. A family describes a group of related graphs. Stata graphs can be categorized into six different families: bar, box, dot, matrix, pie, and twoway. Each family has different plottypes. The twoway family, for instance, has 42 different plottypes, including scatterplots, lineplots, dropline plots, and range plots.

GIF. See *Graphics Interchange Format (GIF)*.

.gph file. Stata stores graphs in .gph files, along with the original data from which the graph was drawn. These .gph files are binary files written in a machine-and-operating-system independent format, which means that .gph files may be read on a Mac, Windows, or Unix computer, regardless of the type of computer on which it was originally created. See [G-4] **Concept: gph files**.

graph region. The graph region is typically larger than the plot region but smaller than the available area. The graph region includes the plot region and the area where the titles and the axis labels occur. See the image of regions in [G-3] *region_options*. Also see *available area* and *plot region*.

Graphics Interchange Format (GIF). Graphics Interchange Format (GIF) is a type of raster image format, developed by CompuServe in 1987. See [G-3] *gif_options*. Also see *image format*, raster image format, and vector image format.

grids. Grids are lines that extend from an axis across the plot region.

gridstyle. *gridstyle* specifies the overall look of grids, such as whether the grid lines extend into the plot region's margin. See [G-4] *gridstyle*.

HSV values. See hue, saturation, and value (HSV) values.

hue, saturation, and value (HSV) values. Hue, saturation, and value (HSV) values are used to specify a color. For example, values 0, 0, 1 specify white. Also see *cyan*, *magenta*, *yellow*, *and key or black (CMYK) values* and *red*, *green*, *and blue (RGB) values*.

- image format, raster image format, and vector image format. An image format is a way of storing a digital image. A raster image format, also known as a bitmap image format, describes the image in terms of pixels. A vector image format describes the image in terms of its individual components such as lines, points, and text. Examples of raster image formats are GIF, JPEG, PNG, and TIFF. Examples of vector image formats are EPS, PDF, PS, and SVG.
- intensity. Color intensity is the brightness of a color. As intensity decreases, the color is paler. Another term for intensity of color is color saturation. See [G-4] colorstyle for how to adjust intensity.
- intensitystyle. intensitystyle specifies the intensity of colors as a percentage from 0 to 100. For example, 0% means no color at all; 100% means full color. intensitystyle is used primarily in scheme files. See [G-4] intensitystyle.
- Joint Photographic Experts Group (JPEG). Joint Photographic Experts Group (JPEG) is a type of raster image format, created in 1992. See [G-3] jpg_options. Also see image format, raster image format, and vector image format.
- **JPEG**. See Joint Photographic Experts Group (JPEG).
- justificationstyle. justificationstyle specifies how text is horizontally aligned in a textbox. Choices include left-justified, centered, or right-justified. See [G-4] justificationstyle.
- legend and legend key. A legend is a table that shows the symbols used in a graph along with the text describing their meaning. A legend key is a symbol and the descriptive text describing the symbol. Stata has a standard legend, a contourline plot legend, and a contour plot legend, controlled by legend(), plegend(), and clegend(), respectively. See [G-3] legend_options and [G-3] clegend_option.
- **legendstyle**. legendstyle defines the look of a legend, which is defined by 14 attributes, including the number of columns or rows of the table, the gaps between lines and columns, and the margin around the legend. See [G-4] legendstyle.
- **linealignmentstyle**. *linealignmentstyle* specifies the alignment of a border or outline for markers, fill areas, bars, and boxes. The line can be placed inside the outline, outside the outline, or centered on the outline. See [G-4] linealignmentstyle.
- linepatternstyle. linepatternstyle specifies the pattern of a line, such as solid line, dashed line, or dotted line. See [G-4] linepatternstyle.
- linestyle. sets the overall pattern, thickness, color and opacity, and alignment of a line. See [G-4] linestyle.
- linewidthstyle. linewidthstyle specifies the thickness of lines, from so thin as to be invisible to very thick. See [G-4] linewidthstyle.
- marginstyle. marginstyle specifies where to include margins (bottom, top, left, right) as well as their size (from no margin to very large). See [G-4] marginstyle.
- marker. A marker is the ink used to mark where points are on a plot. The overall look of a marker is determined by the markerstyle, which consists of the symbol used (symbolstyle), the size of the marker (markersizestyle), and the color of the marker (colorstyle). See [G-4] markerstyle, [G-4] symbolstyle, [G-4] markersizestyle, and [G-4] colorstyle. Also see markerstyle, symbolstyle, markersizestyle, and colorstyle.
- markerlabelstyle. markerlabelstyle specifies the overall look of marker labels by defining the position, gap, angle, size, and color of the marker label. See [G-4] markerlabelstyle.
- markersizestyle. markersizestyle determines the size of markers, which ranges from tiny to huge. You can make the marker any size that you want; see [G-4] size. See [G-4] markersizestyle. Also see marker and symbolstyle.

- **markerstyle**. *markerstyle* defines the five attributes of a marker: the shape of the marker; the size of the marker; the color and opacity of the marker; the interior color and opacity of the marker; and the overall style, thickness, color and opacity, and alignment of the marker's outline. See [G-4] *markerstyle*.
- merged-explicit option. An option allowed with a graph command is called merged-explicit if it is treated as rightmost unless a suboption is specified. The option title() is a merged-explicit option. If you do not specify any suboptions within option title(), then the rightmost rule applies. For example, graph_command ..., title(hello) title(goodbye) will result in the single title of "goodbye" on the graph. If, however, you were to specify graph_command ..., title(hello) title(goodbye, suffix), then the title of "hello goodbye" would appear on the graph. Each merged-explicit option will have documentation on what the merge options are and how they work. See [G-4] Concept: repeated options.
- merged-implicit option. An option allowed with a graph command is called merged-implicit if repeated instances of the same option within a graph command are merged. Examples of merged-implicit options are yline() and xline() for adding horizontal and vertical lines, respectively, to a graph. See [G-4] Concept: repeated options.
- **object**. Graph objects are the building blocks of Stata graphs: plot regions, axes, legends, notes, captions, titles, subtitles, and positional titles. Objects may themselves contain other objects. A plot region may contain several different plots, each of which are objects. A legend contains a key region, which is itself an object.
- **opacity and transparency**. Opacity is the percentage of a color that covers the background color. Opacity varies between 0% (color has no coverage) to 100% (color fully hides the background). The inverse of opacity is transparency, so 0% opacity means completely transparent and 100% opacity means not transparent. See [G-4] *colorstyle* for information on how to adjust opacity.
- **orientationstyle**. *orientationstyle* specifies whether textboxes are horizontal or vertical. See [G-4] *orientationstyle*.

PDF. See Portable Document Format (PDF).

- **plot region**. The plot region is the area enclosed by the axes. It is where data are plotted. This is not to be confused with the graph region, which encompasses the plot region and the area with the titles and axes labels. See the image of regions in [G-3] *region_options*. Also see *available area* and *graph region*.
- **plotregionstyle**. *plotregionstyle* controls the overall look of a plot region and is defined by four sets of attributes: marginstyle, overall areastyle, internal areastyle, and horizontal and vertical positioning of the plot region. See [G-4] *plotregionstyle*.

plottype. See family and plottype.

PNG. See Portable Network Graphics (PNG).

- **Portable Document Format (PDF).** Portable Document Format (PDF) is a vector file format that can be used to represent graphics and documents independent of hardware, software, or operating system. It was developed by Adobe and initially released in 1993. PDF was standardized (ISO) as an open format in 2008. Also see *image format, raster image format, and vector image format*.
- **Portable Network Graphics (PNG)**. Portable Network Graphics (PNG) is a raster image format that is nonpatented and was originally released in 1996. See [G-3] *png_options*. Also see *image format*, raster image format, and vector image format.
- **PostScript** (**PS**). PostScript (PS) is a vector file format that is actually its own language. It was originally created by Adobe Systems in 1984 as a page description language with hopes that it could be used by any printer. Although not all printers support PostScript, it has become a widely

used format supported by many printers, screen rendering programs, and graphic design programs. See [G-3] ps_options. Also see Encapsulated PostScript (EPS) and image format, raster image format, and vector image format.

PS. See PostScript (PS).

pstyle. pstyle specifies the overall look of a plot, which is defined by the look of markers, marker labels, and lines (markerstyle, markerlabelstyle, linestyle); how points are connected by lines (connectstyle); whether missing values cause lines to be broken when connected; the way areas are filled, colored, shaded, and outlined (areastyle); the look of dots in dot plots; and the look of arrowheads. See [G-4] pstyle.

raster image format. See image format, raster image format, and vector image format.

red, green, and blue (RGB) values. Red, green, and blue (RGB) values are a triplet of numbers, each of which specifies, on a scale of 0-255, the amount of red, green, and blue to be mixed. For example, to obtain the following colors, you would use these values:

red	=	255	0	0
green	=	0	255	0
blue	=	0	0	255
white	=	255	255	255
black	=	0	0	0
gray	=	128	128	128
navy	=	26	71	111

The overall scale of the triplet affects intensity, so changing 255 to 128 would keep the color the same but make it dimmer. Also see cyan, magenta, yellow, and key or black (CMYK) values and hue, saturation, and value (HSV) values.

repeated option. A repeated option is an option to a graph command that can be specified more than once. It is unusual for Stata to allow a repeated option for a command, but graph commands are an exception because so many other commands are implemented in terms of graph commands. Repeated options are either rightmost or merged. rightmost instructs Stata to take the rightmost occurrence; merged specifies to merge repeated instances together. See [G-4] Concept: repeated options.

RGB values. See red, green, and blue (RGB) values.

rightmost option. An option allowed with a graph command is called rightmost if an option is repeated within the same graph command, and all but the rightmost occurrence of the option are ignored. msymbol() is an example of a rightmost option. See [G-4] Concept: repeated options. Also see unique option, merged-implicit option, and merged-explicit option.

ringposstyle. ringposstyle, a number from 0 to 100, specifies the distance from the plot region for titles, subtitles, etc. Positioning of titles is controlled by options position(clockposstyle) and ring(ringposstyle). The option position() specifies a direction according to the hours of a clock, whereas the option ring() controls the distance of the title from the plot region. If two titles were specified at the same position(), the title with the larger ring() would be the furthest from the plot region. See [G-4] ringposstyle.

saturation. See intensity.

Scalable Vector Graphics (SVG). Scalable Vector Graphics (SVG) is a vector image format based on XML. SVG is an open standard developed by the World Wide Web Consortium and initially released in 2001. See [G-3] svg_options. Also see image format, raster image format, and vector image format.

- scheme. A scheme specifies the overall look of a graph, which includes everything from foreground color and background color to whether the y axis appears on the left or the right. A scheme is a set of defaults. Stata's default setting is scheme stcolor. Type graph query, schemes to see the list of schemes installed on your computer. See Examples of schemes in [G-4] Schemes intro.
- shadestyle. shadestyle sets the color ([G-4] colorstyle) and intensity ([G-4] intensitystyle) of the color for a filled area. See [G-4] shadestyle.
- style, composite style, and detail style. style specifies a composite of related option settings that together determine the overlook of the graph. Styles come in two forms: detail styles and composite styles. Detail styles specify precisely how an attribute of something looks, and composite styles specify an overall look in terms of detail-style values.

Examples of composite style options are mstyle(symbolstyle), mlabstyle(markerlabelstyle), and lstyle(linestyle), which specify the overall look of symbols, marker labels, and lines, respectively. Note that composite style options all end in "style": mstyle(), mlabstyle(), and lstyle().

Examples of detail styles are mcolor(colorstyle), mlwidth(linewidthstyle), and mlabsize(textsizestyle), which specify the color of an object, the outline thickness, and the size of the label, respectively. Note that the option names do not end in the word style: mcolor(), mlwidth(), and mlabsize().

SVG. See Scalable Vector Graphics (SVG).

- **symbolstyle**. The *symbolstyle* determines the shape of markers. Choices include circles, diamonds, triangles, squares (these four can be different sizes and hollow or not), plus signs, X's (these two can be only different sizes), dots and even an invisible symbol. See [G-4] symbolstyle. Also see marker and markersizestyle.
- Tagged Image File Format (TIFF). Tagged Image File Format (TIFF) is a raster graphics image format created by Aldus Corporation in 1986 and subsequently updated by Adobe Systems after Adobe acquired Aldus. See [G-3] tif_options. Also see image format, raster image format, and vector image format.
- **textbox**. A textbox is one or more lines of text with an optional border around it. Also see *textboxstyle*.
- textboxstyle. Textboxes are defined by 11 attributes such as whether the textbox is vertical or horizontal (orientationstyle); the size of the text (textsizestyle), the color of the text (colorstyle), and whether the text is left-justified, centered, or right-justified (justificationstyle). See [G-4] textboxstyle. Also see orientationstyle, colorstyle, and justificationstyle.
- textsizestyle. textsizestyle specifies the size of text. See [G-4] textsizestyle for choices for the size of text.
- textstyle. textstyle specifies the overall look of text, which is defined by five attributes: whether the text is vertical or horizontal (orientationstyle); the size of the text (textsizestyle); the color of the text (colorstyle); whether the text is left-justified, centered, or right-justified (justificationstyle); and how the text aligns with the baseline (alignmentstyle). See [G-4] textstyle. Also see orientationstyle, textsizestyle, colorstyle, symbolstyle, justificationstyle, and alignmentstyle.
- ticks. Ticks are the marks that appear on axes. See [G-4] tickstyle.
- ticksetstyle. ticksetstyle specifies the overall look of axis ticks, which is determined by the tickstyle, the gridstyle (if a grid is associated with the tickset), and other tick details. See [G-4] ticksetstyle. Also see tickstyle and gridstyle.
- tickstyle. tickstyle specifies the overall look of axis ticks and their labels. Ticks are defined by three attributes: the length of the tick; the line style of the tick; and whether the tick extends out, extends

in, or crosses the axis. Tick labels are defined by two attributes: their size and color. tickstyle also determines the gap between the tick and the tick label. See [G-4] tickstyle.

TIFF. See Tagged Image File Format (TIFF).

transparency. See opacity and transparency.

twoway graph. Twoway graphs are graphs with two dimensions; they display the relationship between the variables in the numeric y and x axes. See [G-2] graph twoway.

unique option. An option allowed with a graph command is called unique if the option may be specified only once. saving() is an example of a unique option. Also see rightmost option, merged-implicit option, and merged-explicit option.

vector image format. See image format, raster image format, and vector image format.
