xtgls - GLS linear model with heteroskedastic and correlated errors

Description Options References Quick start Remarks and examples Also see Menu Stored results Syntax Methods and formulas

Description

xtgls fits panel-data linear models by using feasible generalized least squares. This command allows estimation in the presence of AR(1) autocorrelation within panels and cross-sectional correlation and heteroskedasticity across panels.

Quick start

GLS regression of y on x1, x2, and indicators for levels of categorical variable a using xtset data xtgls y x1 x2 i.a

With heteroskedastic but uncorrelated errors across panels xtgls y x1 x2 i.a, panels(heteroskedastic)

- With heteroskedastic and correlated errors across panels xtgls y x1 x2 i.a, panels(correlated)
- Three-stage GLS with a common first-order autocorrelation within panels xtgls y x1 x2 i.a, panels(correlated) corr(ar1)
- Same as above, but let autocorrelation structure be panel-specific xtgls y x1 x2 i.a, panels(correlated) corr(psar1)

Same as above, but estimate by iterated GLS xtgls y x1 x2 i.a, panels(correlated) corr(psar1) igls

Title

Syntax

xtgls depvar [indepvars] [if] [in] [weight] [, options]

options	Description
Model	
<u>nocons</u> tant	suppress constant term
panels(<u>i</u> id)	use i.i.d. error structure
_ panels(<u>h</u> eteroskedastic)	use heteroskedastic but uncorrelated error structure
_ panels(<u>c</u> orrelated)	use heteroskedastic and correlated error structure
_ <u>c</u> orr(<u>i</u> ndependent)	use independent autocorrelation structure
<u>c</u> orr(<u>a</u> r1)	use AR1 autocorrelation structure
<u>c</u> orr(psar1)	use panel-specific AR1 autocorrelation structure
<u>rho</u> type(<i>calc</i>)	specify method to compute autocorrelation parameter; see <i>Options</i> for details; seldom used
igls	use iterated GLS estimator instead of two-step GLS estimator
force	estimate even if observations unequally spaced in time
SE	
nmk	normalize standard error by $N-k$ instead of N
Reporting	
<u>l</u> evel(#)	set confidence level; default is level(95)
display_options	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Optimization	
optimize_options	control the optimization process; seldom used
<u>coefl</u> egend	display legend instead of statistics

A panel variable must be specified. For correlation structures other than independent, a time variable must be specified. A time variable must also be specified if panels(correlated) is specified. Use xtset; see [XT] xtset. *indepvars* may contain factor variables; see [U] 11.4.3 Factor variables. *depvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

by, collect, and statsby are allowed; see [U] 11.1.10 Prefix commands.

aweights are allowed; see [U] 11.1.6 weight.

coeflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

Model

noconstant; see [R] Estimation options.

panels(*pdist*) specifies the error structure across panels.

panels(iid) specifies a homoskedastic error structure with no cross-sectional correlation. This is the default.

panels(heteroskedastic) specifies a heteroskedastic error structure with no cross-sectional correlation.

panels(correlated) specifies a heteroskedastic error structure with cross-sectional correlation. If p(c) is specified, you must also specify a time variable (use xtset). The results will be based on a generalized inverse of a singular matrix unless $T \ge m$ (the number of periods is greater than or equal to the number of panels).

corr(corr) specifies the assumed autocorrelation within panels.

corr(independent) specifies that there is no autocorrelation. This is the default.

corr(ar1) specifies that, within panels, there is AR(1) autocorrelation and that the coefficient of the AR(1) process is common to all the panels. If c(ar1) is specified, you must also specify a time variable (use xtset).

corr(psar1) specifies that, within panels, there is AR(1) autocorrelation and that the coefficient of the AR(1) process is specific to each panel. psar1 stands for panel-specific AR(1). If c(psar1) is specified, a time variable must also be specified; use xtset.

rhotype(calc) specifies the method to be used to calculate the autocorrelation parameter:

regress	regression using lags; the default
dw	Durbin–Watson calculation
freg	regression using leads
nagar	Nagar calculation
theil	Theil calculation
tscorr	time-series autocorrelation calculation

All the calculations are asymptotically equivalent and consistent; this is a rarely used option.

- igls requests an iterated GLS estimator instead of the two-step GLS estimator for a nonautocorrelated model or instead of the three-step GLS estimator for an autocorrelated model. The iterated GLS estimator converges to the MLE for the corr(independent) models but does not for the other corr() models.
- force specifies that estimation be forced even though the time variable is not equally spaced. This is relevant only for correlation structures that require knowledge of the time variable. These correlation structures require that observations be equally spaced so that calculations based on lags correspond to a constant time change. If you specify a time variable indicating that observations are not equally spaced, the (time dependent) model will not be fit. If you also specify force, the model will be fit, and it will be assumed that the lags based on the data ordered by the time variable are appropriate.

SE

nmk specifies that standard errors be normalized by N - k, where k is the number of parameters estimated, rather than N, the number of observations. Different authors have used one or the other normalization. Greene (2018, 313) remarks that whether a degree-of-freedom correction improves the small-sample properties is an open question.

Reporting

level(#); see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(% fmt), pformat(% fmt), sformat(% fmt), and nolstretch; see [R] Estimation options. Optimization

optimize_options control the iterative optimization process. These options are seldom used.

<u>iterate(#)</u> specifies the maximum number of iterations. When the number of iterations equals #, the optimization stops and presents the current results, even if convergence has not been reached. The default is iterate(100).

tolerance(#) specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to #, the optimization process is stopped. tolerance(1e-7) is the default.

log and nolog specify whether to display the iteration log. The iteration log is displayed by default unless you used set iterlog off to suppress it; see set iterlog in [R] set iter.

The following option is available with xtgls but is not shown in the dialog box:

coeflegend; see [R] Estimation options.

Remarks and examples

stata.com

Remarks are presented under the following headings:

Introduction Heteroskedasticity across panels Correlation across panels (cross-sectional correlation) Autocorrelation within panels

Introduction

Information on GLS can be found in Greene (2018), Maddala and Lahiri (2006), Davidson and MacKinnon (1993), and Judge et al. (1985).

If you have many panels relative to periods, see [XT] **xtreg** and [XT] **xtgee**. **xtgee**, in particular, provides capabilities similar to those of **xtgls** but does not allow cross-sectional correlation. On the other hand, **xtgee** allows a richer description of the correlation within panels as long as the same correlations apply to all panels. **xtgls** provides two unique features:

1. Cross-sectional correlation may be modeled (panels(correlated)).

2. Within panels, the AR(1) correlation coefficient may be unique (corr(psar1)).

xtgls allows models with heteroskedasticity and no cross-sectional correlation, but, strictly speaking, xtgee does not. xtgee with the vce(robust) option relaxes the assumption of equal variances, at least as far as the standard error calculation is concerned.

Also, xtgls, panels(iid) corr(independent) nmk is equivalent to regress.

The nmk option uses n - k rather than n to normalize the variance calculation.

To fit a model with autocorrelated errors (corr(ar1) or corr(psar1)), the data must be equally spaced in time. To fit a model with cross-sectional correlation (panels(correlated)), panels must have the same number of observations (be balanced).

The equation from which the models are developed is given by

$$y_{it} = \mathbf{x}_{it}\boldsymbol{\beta} + \epsilon_{it}$$

where i = 1, ..., m is the number of units (or panels) and $t = 1, ..., T_i$ is the number of observations for panel *i*. This model can equally be written as

$$egin{bmatrix} \mathbf{y}_1 \ \mathbf{y}_2 \ \vdots \ \mathbf{y}_m \end{bmatrix} = egin{bmatrix} \mathbf{X}_1 \ \mathbf{X}_2 \ \vdots \ \mathbf{X}_m \end{bmatrix} oldsymbol{eta} + egin{bmatrix} oldsymbol{\epsilon}_1 \ oldsymbol{\epsilon}_2 \ \vdots \ oldsymbol{\epsilon}_m \end{bmatrix}$$

The variance matrix of the disturbance terms can be written as

$$E[\boldsymbol{\epsilon}\boldsymbol{\epsilon}'] = \boldsymbol{\Omega} = \begin{bmatrix} \sigma_{1,1}\boldsymbol{\Omega}_{1,1} & \sigma_{1,2}\boldsymbol{\Omega}_{1,2} & \cdots & \sigma_{1,m}\boldsymbol{\Omega}_{1,m} \\ \sigma_{2,1}\boldsymbol{\Omega}_{2,1} & \sigma_{2,2}\boldsymbol{\Omega}_{2,2} & \cdots & \sigma_{2,m}\boldsymbol{\Omega}_{2,m} \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_{m,1}\boldsymbol{\Omega}_{m,1} & \sigma_{m,2}\boldsymbol{\Omega}_{m,2} & \cdots & \sigma_{m,m}\boldsymbol{\Omega}_{m,m} \end{bmatrix}$$

For the $\Omega_{i,j}$ matrices to be parameterized to model cross-sectional correlation, they must be square (balanced panels).

In these models, we assume that the coefficient vector β is the same for all panels and consider a variety of models by changing the assumptions on the structure of Ω .

For the classic OLS regression model, we have

$$E[\epsilon_{i,t}] = 0$$

$$Var[\epsilon_{i,t}] = \sigma^{2}$$

$$Cov[\epsilon_{i,t}, \epsilon_{j,s}] = 0 \quad \text{if } t \neq s \text{ or } i \neq j$$

This amounts to assuming that Ω has the structure given by

	$\lceil \sigma^2 \mathbf{I} \rceil$	$0 \\ \sigma^2 \mathbf{I}$	• • •	ך 0
~	0	$\sigma^2 \mathbf{I}$		0
$\Omega =$:	÷	·	:
	0	0		$\sigma^2 \mathbf{I}$

whether or not the panels are balanced (the **0** matrices may be rectangular). The classic OLS assumptions are the default panels(iid) and corr(independent) options for this command.

Heteroskedasticity across panels

In many cross-sectional datasets, the variance for each of the panels differs. It is common to have data on countries, states, or other units that have variation of scale. The heteroskedastic model is specified by including the panels(heteroskedastic) option, which assumes that

$$\boldsymbol{\Omega} = \begin{bmatrix} \sigma_1^2 \mathbf{I} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \sigma_2^2 \mathbf{I} & \cdots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & \sigma_m^2 \mathbf{I} \end{bmatrix}$$

Example 1

Greene (2012, 1112) reprints data in a classic study of investment demand by Grunfeld and Griliches (1960). Below we allow the variances to differ for each of the five companies.

stock	.3378129	.0302254	11.18	0.000	.2785722	.3970535
_cons	-36.2537	6.124363	-5.92	0.000	-48.25723	-24.25017

Correlation across panels (cross-sectional correlation)

We may wish to assume that the error terms of panels are correlated, in addition to having different scale variances. The variance structure is specified by including the panels(correlated) option and is given by

	$\lfloor \sigma_{m,1} \mathbf{I} \rfloor$	$\sigma_{m,2}\mathbf{I}$		$\sigma_m^2 \mathbf{I}$
			••.	
$\mathbf{\Omega} =$	02,11	0.21		02,m -
	$\sigma_{2,1}\mathbf{I}$	$\sigma_2^2 \mathbf{I}$		$\sigma_{2,m}\mathbf{I}$
	$\int \sigma_1^2 \mathbf{I}$	$\sigma_{1,2}\mathbf{I}$	• • •	$\sigma_{1,m}\mathbf{I}$

Because we must estimate cross-sectional correlation in this model, the panels must be balanced (and $T \ge m$ for valid results). A time variable must also be specified so that xtgls knows how the observations within panels are ordered. xtset shows us that this is true.

Coefficients: Panels: Correlation:	heteroskedas	tic with cro		onal cor	relation		
Estimated cova	ariances	= 15		Number	of obs	=	100
Estimated auto	ocorrelations	= 0		Number	of group	s =	5
Estimated coef	fficients	= 3		Time pe	riods	=	20
				Wald ch	i2(2)	=	558.51
Log likelihood	1	= -515.4222		Prob >	chi2	=	0.0000
invest	Coefficient	Std. err.	z	P> z	[95%	conf.	interval]
market	.023631	.004291	5.51	0.000	.0152	207	.0320413
stock	.1709472	.0152526	11.21	0.000	.1410	526	.2008417
_cons	-2.216508	1.958845	-1.13	0.258	-6.055	774	1.622759

Here the log likelihood is reported in the header of the output.

Autocorrelation within panels

The individual identity matrices along the diagonal of Ω may be replaced with more general structures to allow for serial correlation. xtgls allows three options so that you may assume a structure with corr(independent) (no autocorrelation); corr(ar1) (serial correlation where the correlation parameter is common for all panels); or corr(psar1) (serial correlation where the correlation parameter is unique for each panel).

The restriction of a common autocorrelation parameter is reasonable when the individual correlations are nearly equal and the time series are short.

If the restriction of a common autocorrelation parameter is reasonable, this allows us to use more information in estimating the autocorrelation parameter to produce a more reasonable estimate of the regression coefficients.

When you specify corr(ar1) or corr(psar1), the iterated GLS estimator does not converge to the MLE.

Example 4

If corr(ar1) is specified, each group is assumed to have errors that follow the same AR(1) process; that is, the autocorrelation parameter is the same for all groups.

Stored results

xtgls stores the following in e():

Scalars	
e(N)	number of observations
e(N_ic)	number of observations used to compute information criteria
e(N_g)	number of groups
e(N_t)	number of periods
e(N_miss)	number of missing observations
e(n_cf)	number of estimated coefficients
e(n_cv)	number of estimated covariances
e(n_cr)	number of estimated correlations
e(df)	degrees of freedom
e(df_pear)	degrees of freedom for Pearson χ^2
e(df_ic)	degrees of freedom for information criteria
e(11)	log likelihood
e(chi2)	χ^2
e(g_min)	smallest group size
e(g_avg)	average group size
e(g_max)	largest group size
e(rank)	rank of e(V)
e(rc)	return code
Macros	
e(cmd)	xtgls
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(ivar)	variable denoting groups
e(tvar)	variable denoting time within groups
e(coefftype)	estimation scheme
e(corr)	correlation structure
e(vt)	panel option
e(rhotype)	type of estimated correlation
e(wtype)	weight type
e(wexp)	weight expression
e(title)	title in estimation output
e(chi2type)	Wald; type of model χ^2 test
e(rho)	ho
e(properties)	b V
e(predict)	program used to implement predict
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved
Matrices	
e(b)	coefficient vector
e(Sigma)	$\widehat{\Sigma}$ matrix
e(V)	variance – covariance matrix of the estimators
	variance covariance matrix of the estimators
Functions	1
e(sample)	marks estimation sample

In addition to the above, the following is stored in r():

Matrices r(table)

matrix containing the coefficients with their standard errors, test statistics, *p*-values, and confidence intervals

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

Methods and formulas

The GLS results are given by

$$\widehat{\boldsymbol{\beta}}_{\text{GLS}} = (\mathbf{X}' \widehat{\boldsymbol{\Omega}}^{-1} \mathbf{X})^{-1} \mathbf{X}' \widehat{\boldsymbol{\Omega}}^{-1} \mathbf{y}$$
$$\widehat{\text{Var}}(\widehat{\boldsymbol{\beta}}_{\text{GLS}}) = (\mathbf{X}' \widehat{\boldsymbol{\Omega}}^{-1} \mathbf{X})^{-1}$$

For all our models, the Ω matrix may be written in terms of the Kronecker product:

$$\mathbf{\Omega} = \mathbf{\Sigma}_{m \times m} \otimes \mathbf{I}_{T_i \times T_i}$$

The estimated variance matrix is obtained by substituting the estimator Σ for Σ , where

$$\widehat{\boldsymbol{\Sigma}}_{i,j} = \frac{\widehat{\boldsymbol{\epsilon}}_i \,' \, \widehat{\boldsymbol{\epsilon}}_j}{T}$$

The residuals used in estimating Σ are first obtained from OLS regression. If the estimation is iterated, residuals are obtained from the last fitted model.

Maximum likelihood estimates may be obtained by iterating the FGLS estimates to convergence for models with no autocorrelation, corr(independent).

The GLS estimates and their associated standard errors are calculated using $\widehat{\Sigma}^{-1}$. As Beck and Katz (1995) point out, the Σ matrix is of rank at most min(T, m) when you use the panels(correlated) option. For the GLS results to be valid (not based on a generalized inverse), T must be at least as large as m, as you need at least as many period observations as there are panels.

Beck and Katz (1995) suggest using OLS parameter estimates with asymptotic standard errors that are corrected for correlation between the panels. This estimation can be performed with the xtpcse command; see [XT] xtpcse.
